

MiniMines Sales Hub

Product Description Document (v2)

1. System Overview

The MiniMines Sales Hub is an AI-driven, data-aggregation platform designed to help the sales team identify, prioritize, and reach out to the most valuable procurement targets. The platform ingests massive amounts of unstructured trade data (EXIM) and public regulatory datasets (CPCB EPR targets), normalizes them, and applies a proprietary scoring engine to output actionable lead lists.

2. EPR Producer Intelligence (Engine v2)

The EPR module identifies battery producers with unmet recycling obligations. The engine was completely redesigned (v2) to handle real-world data anomalies found in the CPCB database.

2.1 Log-Anchor Scoring

To prevent extreme outliers (like a single 82,000-tonne producer) from collapsing the scores of the rest of the market, the engine uses a **log1p anchor-band transform**. This means scores are absolute, not relative. Adding or removing a company never arbitrarily changes another company's grade.

2.2 Material-Aware Data Model

The system tracks obligations across specific battery materials (Lithium, Cobalt, Nickel, Manganese). A 'coverage factor' ensures that multi-material majors rank appropriately higher than single-material shell companies.

2.3 Core Business Logic

The fundamental rule remains: **High obligation + low credits = highest grade**. Companies with the largest unmet recycling targets are placed at the top of the sales pipeline.

3. EXIM Trade Intelligence

The EXIM module processes raw customs records to identify active buyers and suppliers in the market.

Attractiveness-to-Trade (ATT) Score

The ATT score ranks entities based on volume, pricing, market structure, trend trajectory, and regulatory freedom (EASE). Like the EPR engine, it utilizes log-anchor bounds derived from real production data (over 107,000 shipments).

4. Entity Resolution & NLP

The platform uses advanced NLP to clean and deduplicate company names, mitigating the fragmentation caused by slight spelling variations in customs data. In the EPR module, the CPCB Registration Number acts as the primary merge key, with name tokenization as a fallback.
